SQL *Essentials*

Roadmap

RDBMS
ER Model

SQL Server
DDL

DML
Operator

Function
SQL Clause

Join data

Sub Query

Best
Practice

What we will explore today?

Database

- What is RDBMS?
- What is DBMS?
- Database Schema
- Database Instance

Entity Relation Model

- What is ER Model?
- What is Entity?
- Cardinality?
- Relationships
- Convert ER model to schema

What is DataBase?

- database is an organized collection of data, typically store & accessed electronically from a computer system or electronic device.

What kind of data is store in DB?

- UserName, Password, Email, Address, Salary ...
- Image, Videos...
- Almost everything “digital” can be storage on database

What is DBMS?

- A database management system is **software** for **managing databases**
- Control access to the databases
- Create, modified, delete databases
- Manipulate data (storage, retrieve, report)

What is RDBMS?

- RDBMS store data in form of table, table contains many columns & rows.
- Use “Query” to communicate with DBMS we can insert , delete, update data in DataBase.

Type of DBMS

- Relational database.
- Object oriented database.
- Hierarchical database.
- Network database.

It's all about table

Column / Field / Attribute				Table
<u>ID</u>	Name	Address	Price	
1	Sơn Tùng	Thủ Đức	10,000\$	
2	Binz	Quận 9	10,000\$	
3	Mono	Quận 3	7,000\$	
4	Mỹ Tâm	Quận 1	12,000\$	

Row Record Tuple

Relational database have many
tables. Table contains many
columns & rows

Database Schema

Singer(ID, Name, Address, Show)

<u>ID</u>	Name	Address	Price
1	Sơn Tùng	Thủ Đức	10,000\$
2	Binz	Quận 9	10,000\$
3	Mono	Quận 3	7,000\$
4	Mỹ Tâm	Quận 1	12,000\$

Schema is describe how the data
should **look like**

It's **not hold any data**

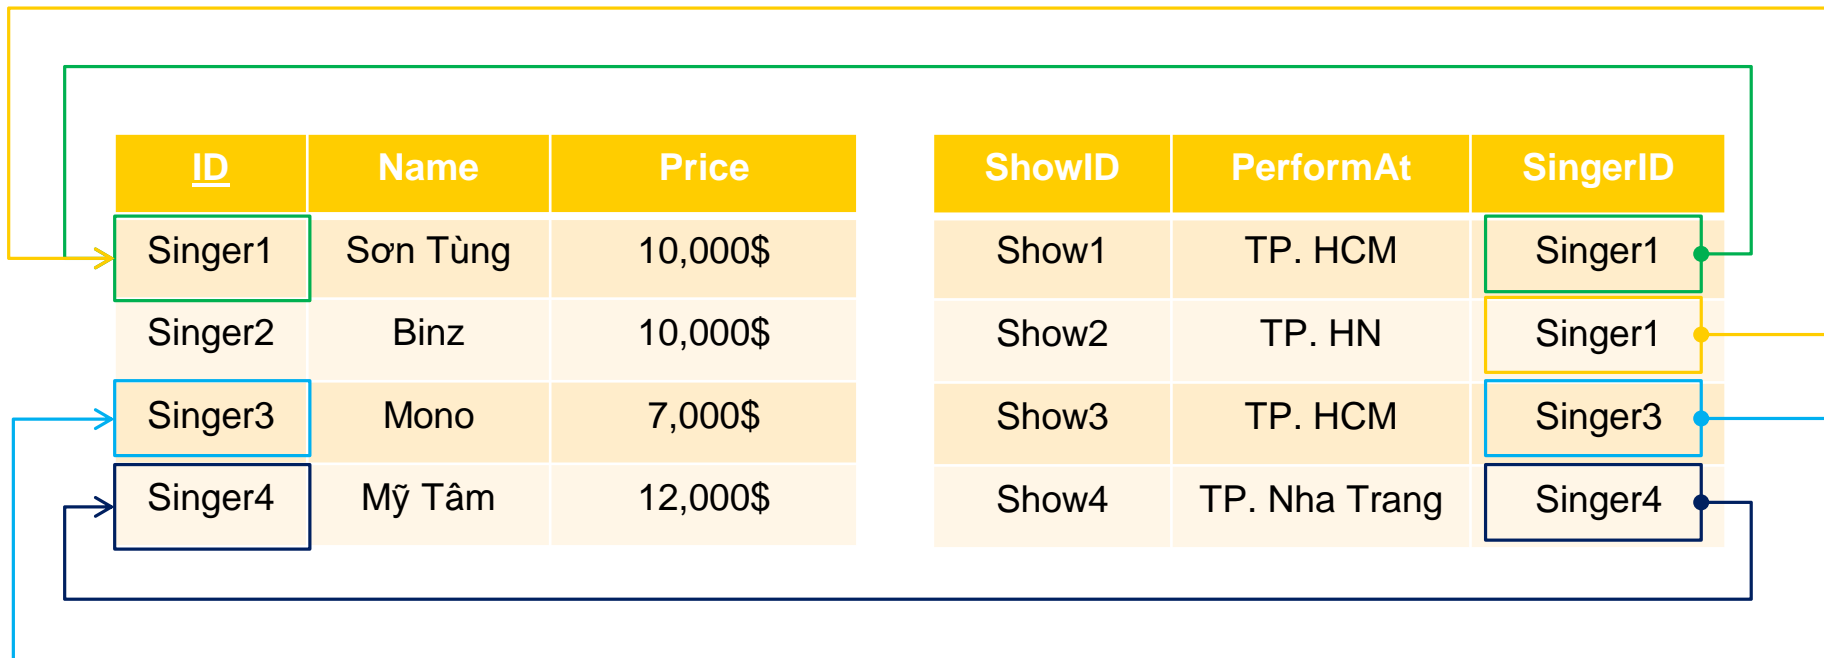

Database instance

<u>ID</u>	Name	Address	Price
1	Sơn Tùng	Thủ Đức	10,000\$
2	Binz	Quận 9	10,000\$
3	Mono	Quận 3	7,000\$
4	Mỹ Tâm	Quận 1	12,000\$

Relational database concept

Database Schema

<u>ID</u>	Name	Price
Singer1	Sơn Tùng	10,000\$
Singer2	Binz	10,000\$
Singer3	Mono	7,000\$
Singer4	Mỹ Tâm	12,000\$

ShowID	PerformAt	SingerID
Show1	TP. HCM	Singer1
Show2	TP. HN	Singer1
Show3	TP. HCM	Singer3
Show4	TP. Nha Trang	Singer4

Why don't we just use one table?

<u>ID</u>	Name	Price
Singer1	Sơn Tùng	10,000\$
Singer2	Binz	10,000\$
Singer3	Mono	7,000\$
Singer4	Mỹ Tâm	12,000\$

ShowID	PerformAt	SingerID
Show1	TP. HCM	Singer1
Show2	TP. HN	Singer1
Show3	TP. HCM	Singer3
Show4	TP. Nha Trang	Singer4

ShowID	PerformAt	SingerID	Name	Price
Show1	TP. HCM	Singer1	Sơn Tùng	10,000\$
Show2	TP. HN	Singer1	Sơn Tùng	10,000\$
Show3	TP. HCM	Singer3	Mono	7,000\$
Show4	TP. Nha Trang	Singer4	Mỹ Tâm	12,000\$

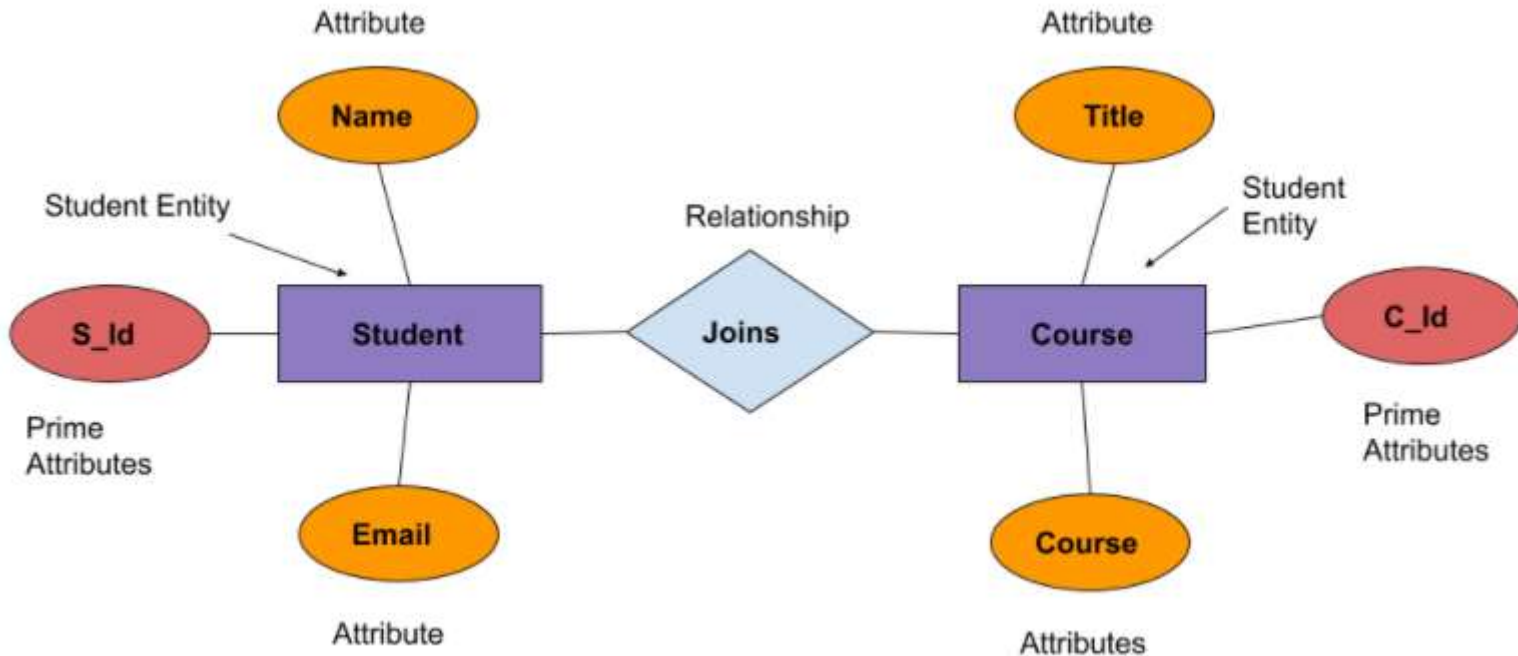

Some specific system use RDBMS

- MySQL
- PostgreSQL
- MariaDB
- Microsoft SQL Server
- Oracle Database
- etc...

What is ER Model?

ER model is a **conceptual design**
design for the database.
representation of **crelationships**
between data.

Why we Need it?

- ER Model **visualize** the **design** and form the **overall view** of the database

Strong entity vs week entity

Strong Entity

- Has primary key
- **NOT** depend on other entity

Strong Entity

Week entity

- Has partial discriminator key
- **Depend** on other entity

Week Entity

Entity Attribute

- It's describes the **characteristics** of an entity
- ex: Student: Name, Phone, Grate, ...

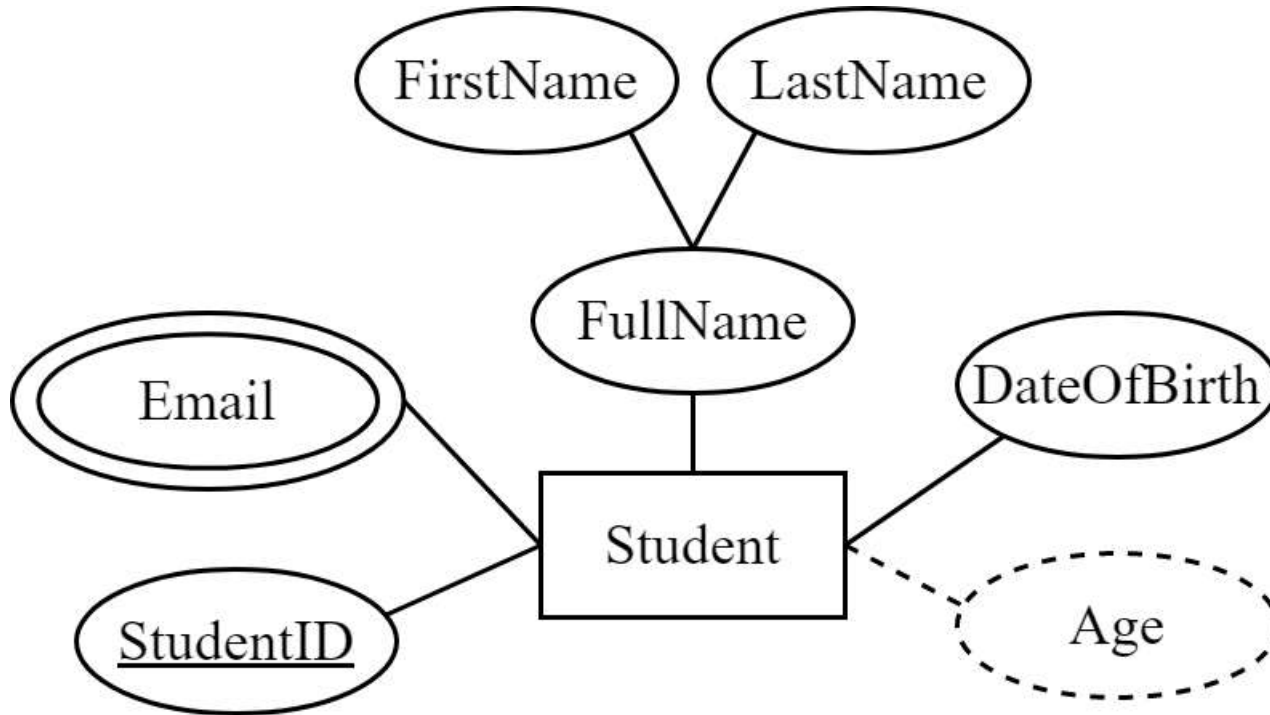

ER Notation

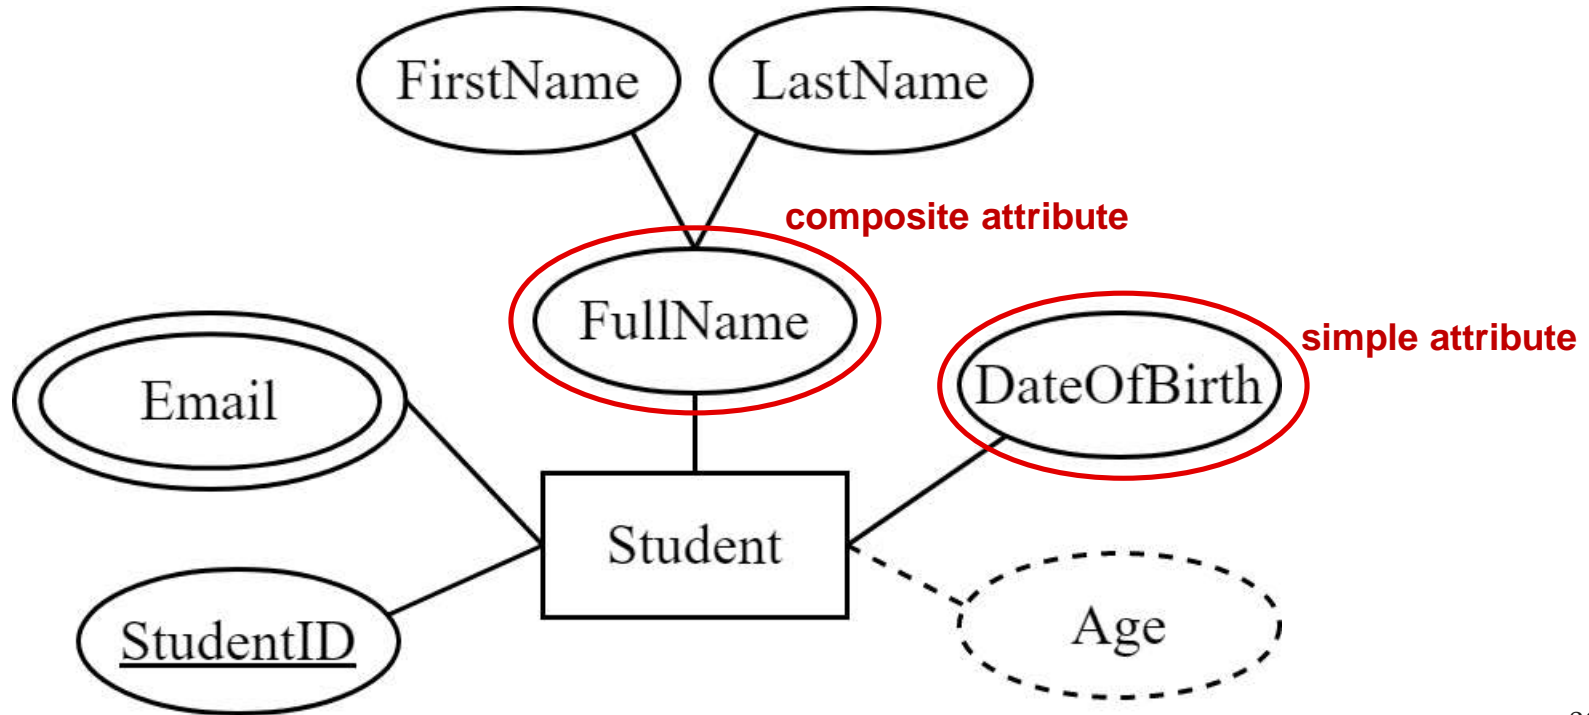

Student entity

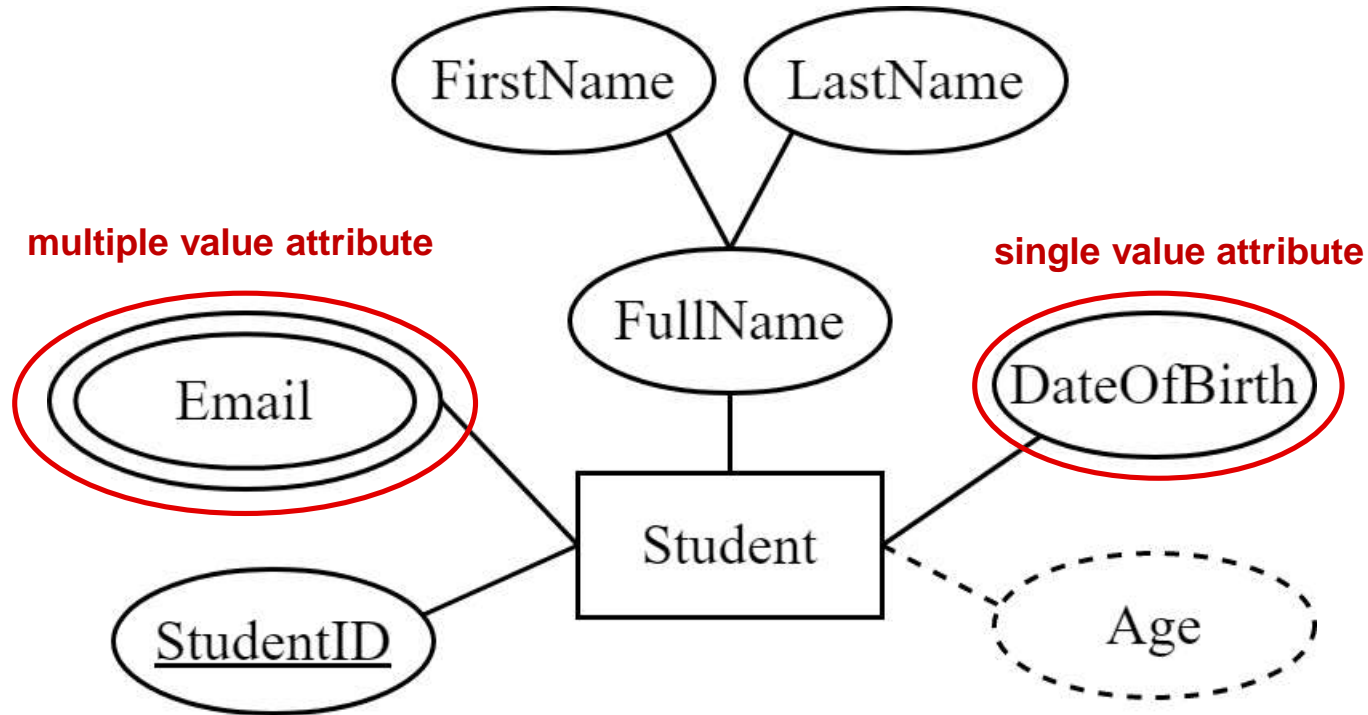

Simple & Composite attribute

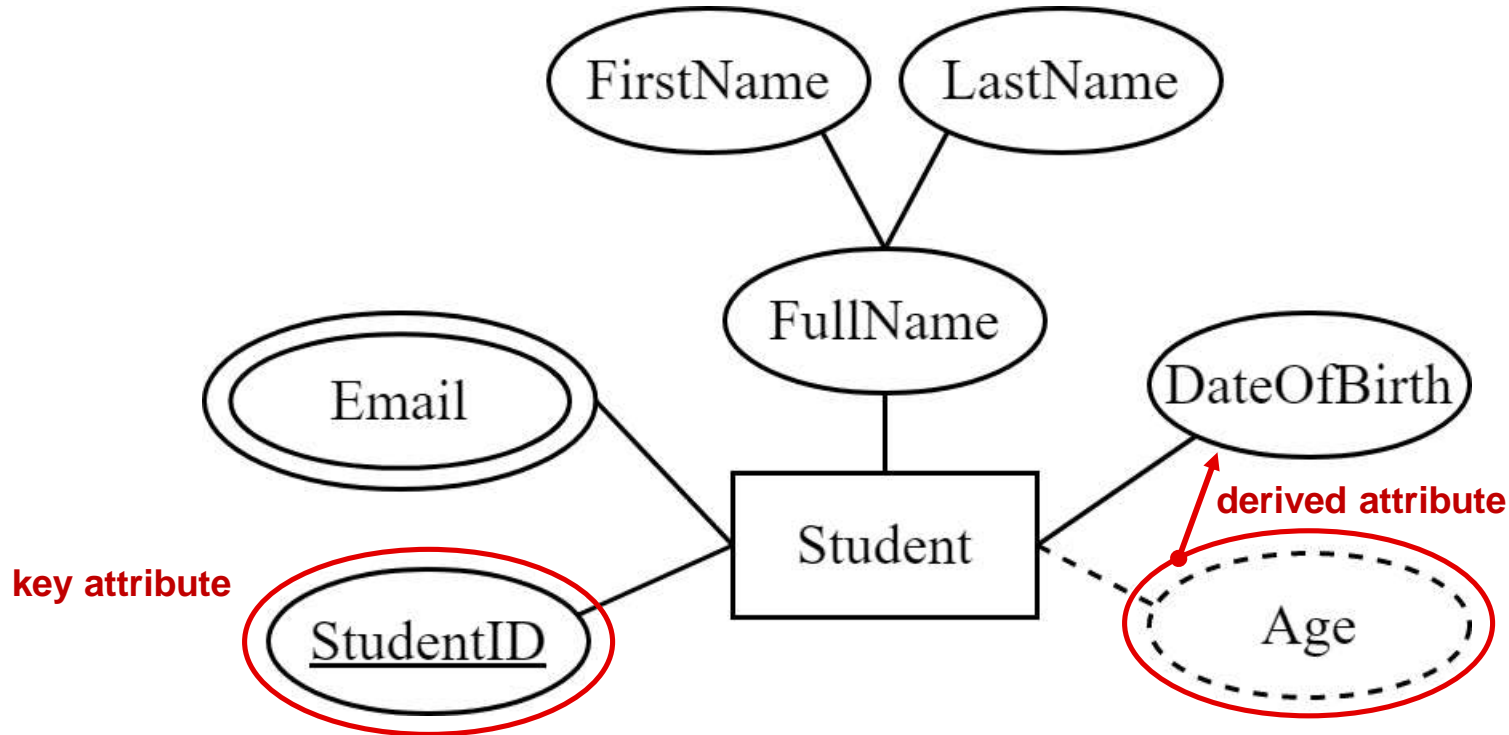

Single & Multiple value attribute

Key & Derived attribute

Practice draw entity & attribute

Draw entity Customer with requirement:

- Address(city, district, street)
- Many PhoneNumber
- FullName(FirstName, LastName)
- DateOfBirth
- Age

Cardinality

Cardinality describes a **relationship** between two entities

- one to one
- many to one
- one to many
- many to many

Cardinalities

Cardinalities

-  Mandatory One
-  Mandatory Many
-  Optional One
-  Optional Many

One to One

- Person have one ID Card

- Person have one Heart

Many-to-One or One-to-Many

- Person have 0 or many BankAccount, a BankAccount belong to one Person

- Class have 1 or many Student, Student must be in one Class

Many-to-Many

- Student study many Course, Courses can learn by 0 or many Student

Practice 1

ex1: Customer can have one or many Address, One Address can belong to zero or many customer

Practice 2

ex2: User can sent zero or many message to Other User. User received zero or many message from other User

Entity relationships

- describes how many entities are participant & how they are related

Unary relationship

- There **only one entity** participant in the relationship

Binary relationship

- There **2 different entity** participant in the relationship

Ternary relationship

- There 3 **different entity** participant in the relationship

N-nary relationship

- There N **different entity** participant in the relationship

design Shopee ER Model

- **Customer** have info(name, address, phone, email, dateOfBirth...etc)
- Customer can have many Order
- **Order**(total amount, delivery address, dateDelivery)
- **Order** have many **Product**(ProductName, with quantity, price, discount)
- **Product** can belong to many Order

Convert ER Model to database schema?

Simple attribute entity

Student(StudentID, FullName, DateOfBirth)

<u>StudentID</u>	FullName	DateOfBirth
1	Snoop Dog	2/19/2000
2	The Rock	2/16/1999

Multiple value attribute

Student(StudentID, FullName, DateOfBirth)

StudentEmail(StudentID, Email)

Student(StudentID, FullName,
DateOfBirth)

StudentEmail(StudentID, Email)

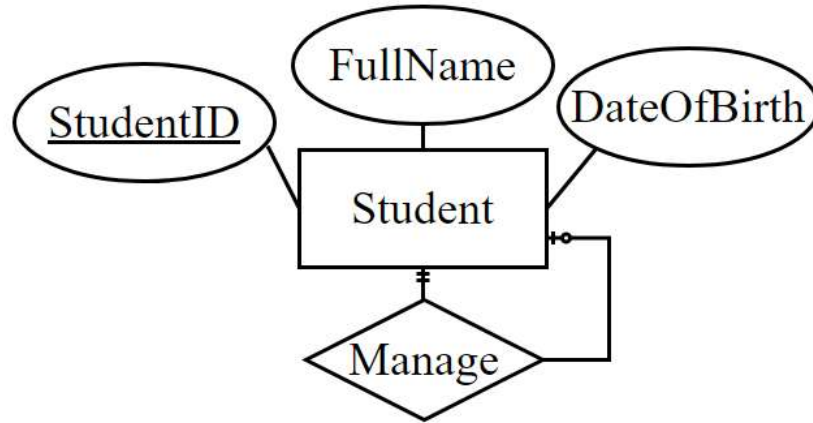

<u>StudentID</u>	FullName	DateOfBirth
1	Snoop Dog	2/19/2000
2	The Rock	2/16/1999

<u>StudentID</u>	<u>Email</u>
1	snoop@high.com
1	snoop@low.com
2	power@man.com
2	supper@man.com
3	test@man.com

Unary one to one(optional)

Student(StudentID, FullName, DateOfBirth, ManageID)

Unary one to many

Employee(EmployeeID, Name, Address, ManagerID)

Employee(EmployeeID, Name, Address, ManagerID)

EmployeeID	Name	Address	ManagerID
1	Việt CEO	98833 Cardinal Park	NULL
2	Nam CTO	21289 Susan Crossing	1
3	Tiến COO	25519 Hermina Alley	1
4	Huy Culi	936 Michigan Alley	2

Binary one to one(optional)

Student(StudentID, Name)

Class(ClassID, ManagerID, Grade)

Binary one to many

Person(ID, Name)

BankAccount(Number, PersonID, ValidDate)

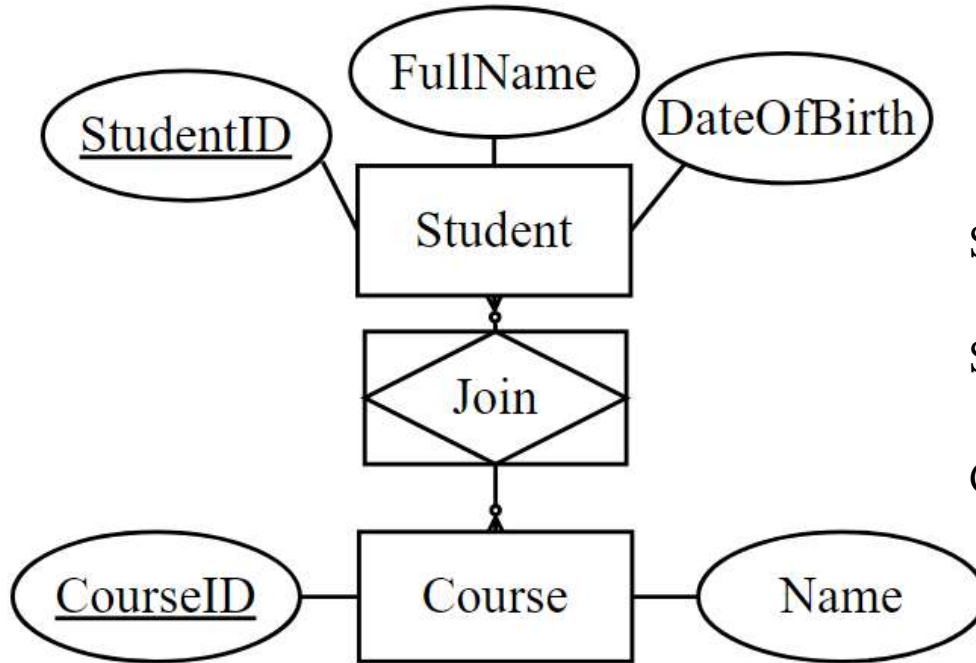

Person(**ID**, Name)

BankAccount(Number, PersonID, ValidDate)

<u>ID</u>	Name	<u>Number</u>	PersonID	ValidDate
1	Huy	111111	1	4/27/1999
2	Dũng	222222	1	8/26/1994
3	Hùng	123456	2	2/13/1998

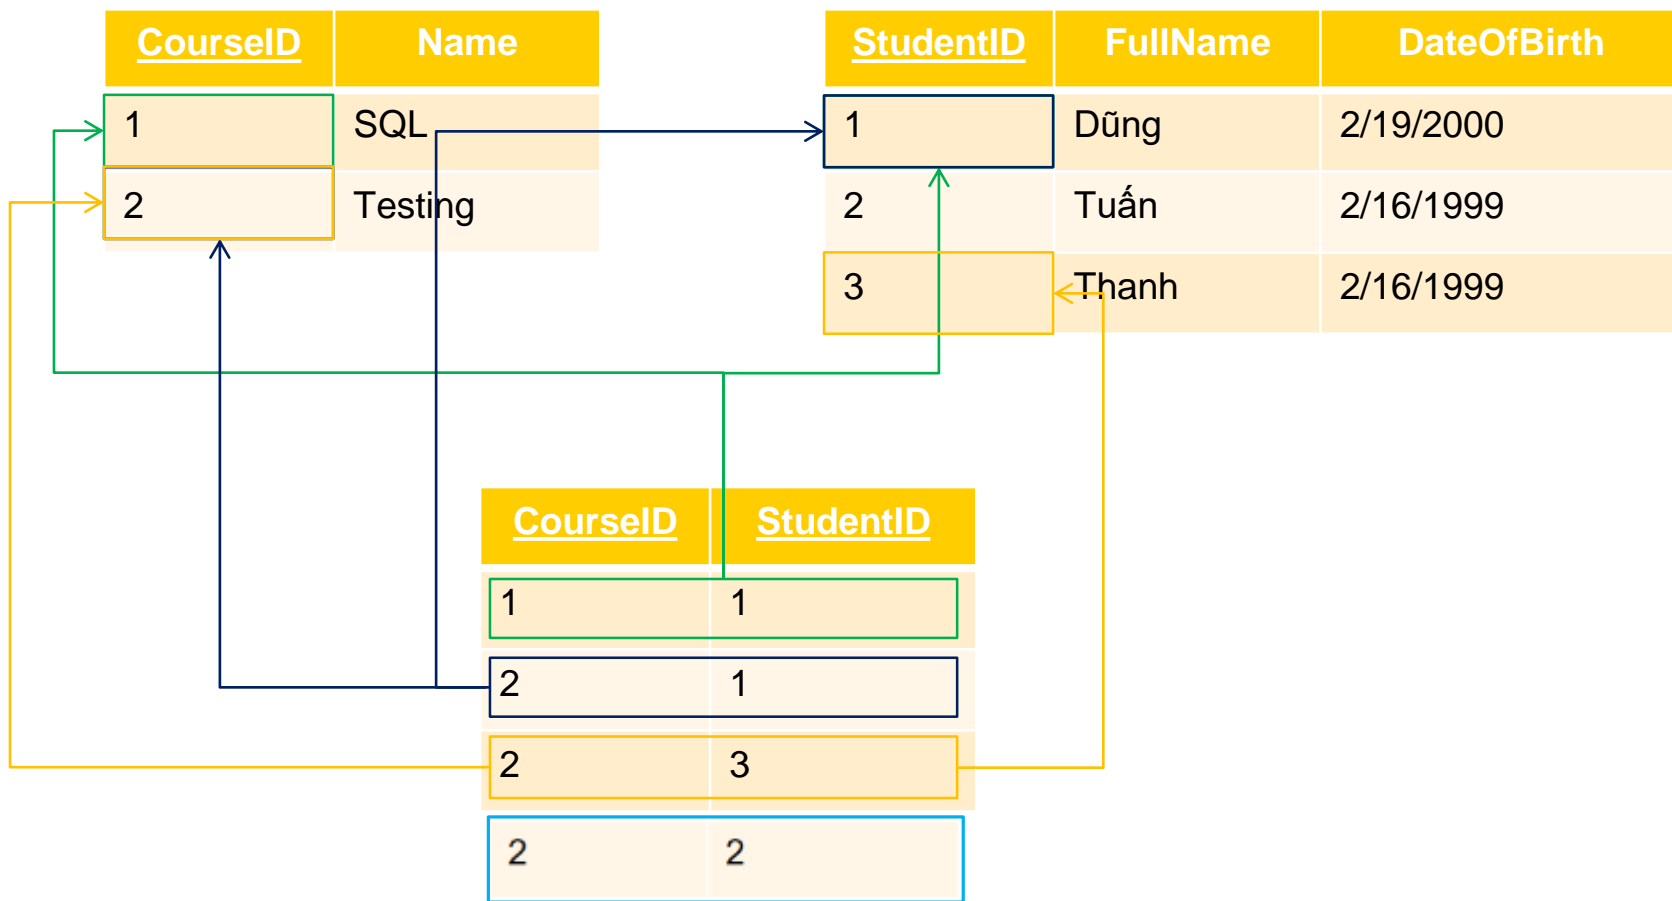

Binary many to many

Student(StudentID, FullName, DateOfBirth)

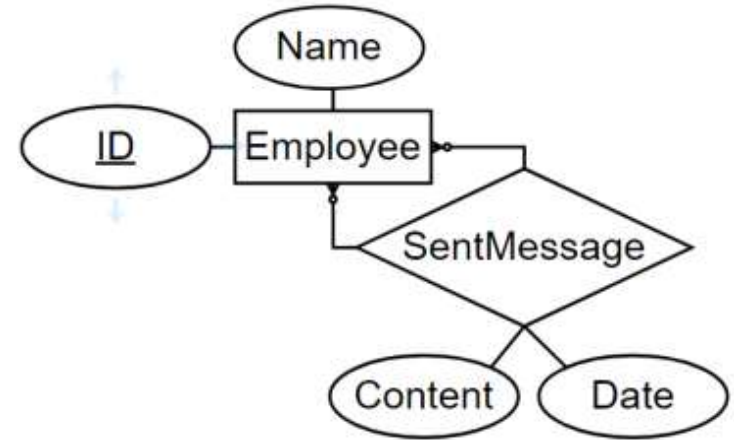

StudentCourses(StudentID, CourseID)

Course(CourseID, Name)

Unary many to many

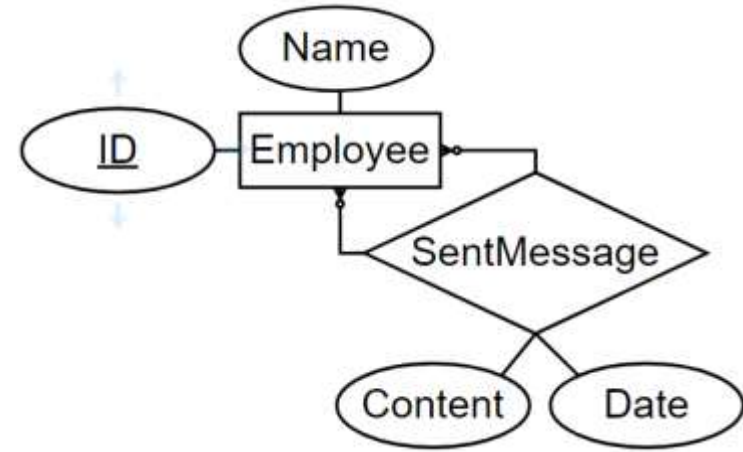

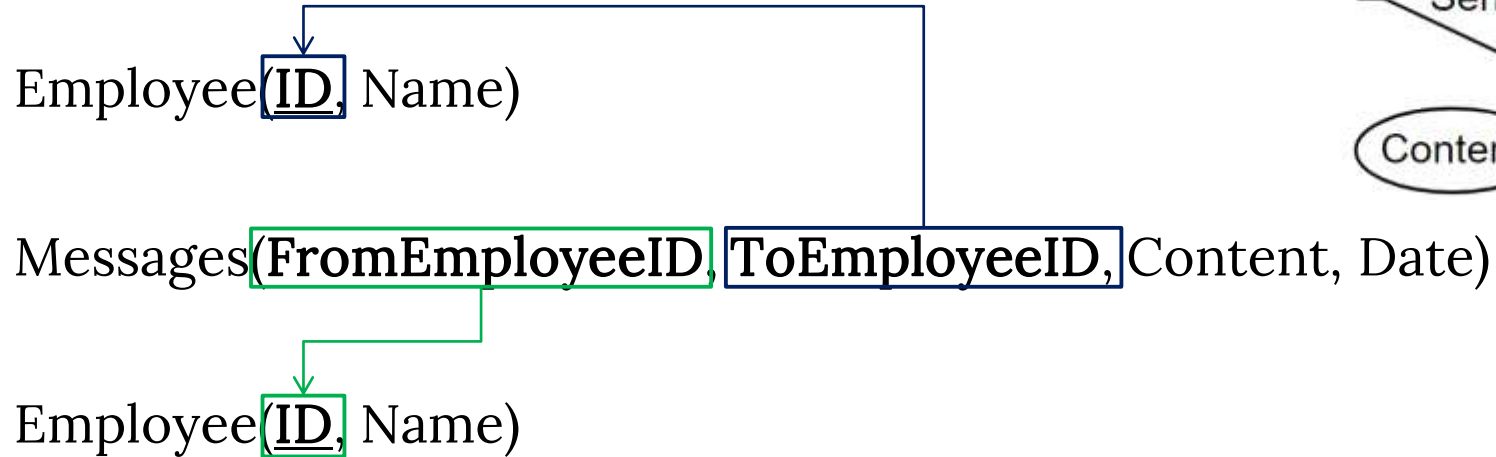

Employee(ID, Name)

Messages(FromEmployeeID, ToEmployeeID, Content, Date)

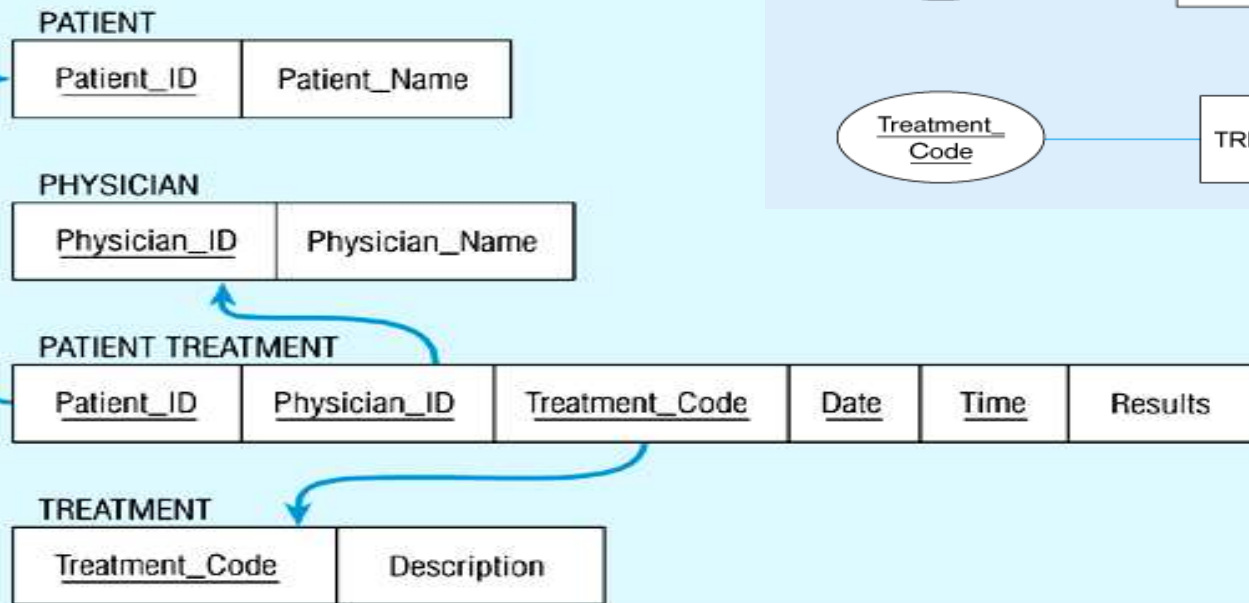

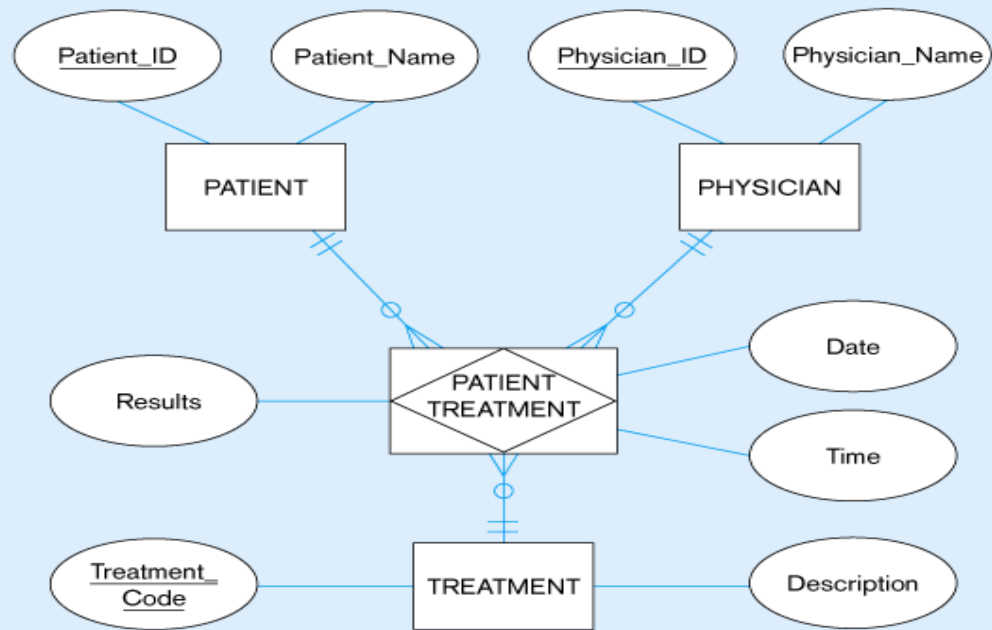

Make you ease to see

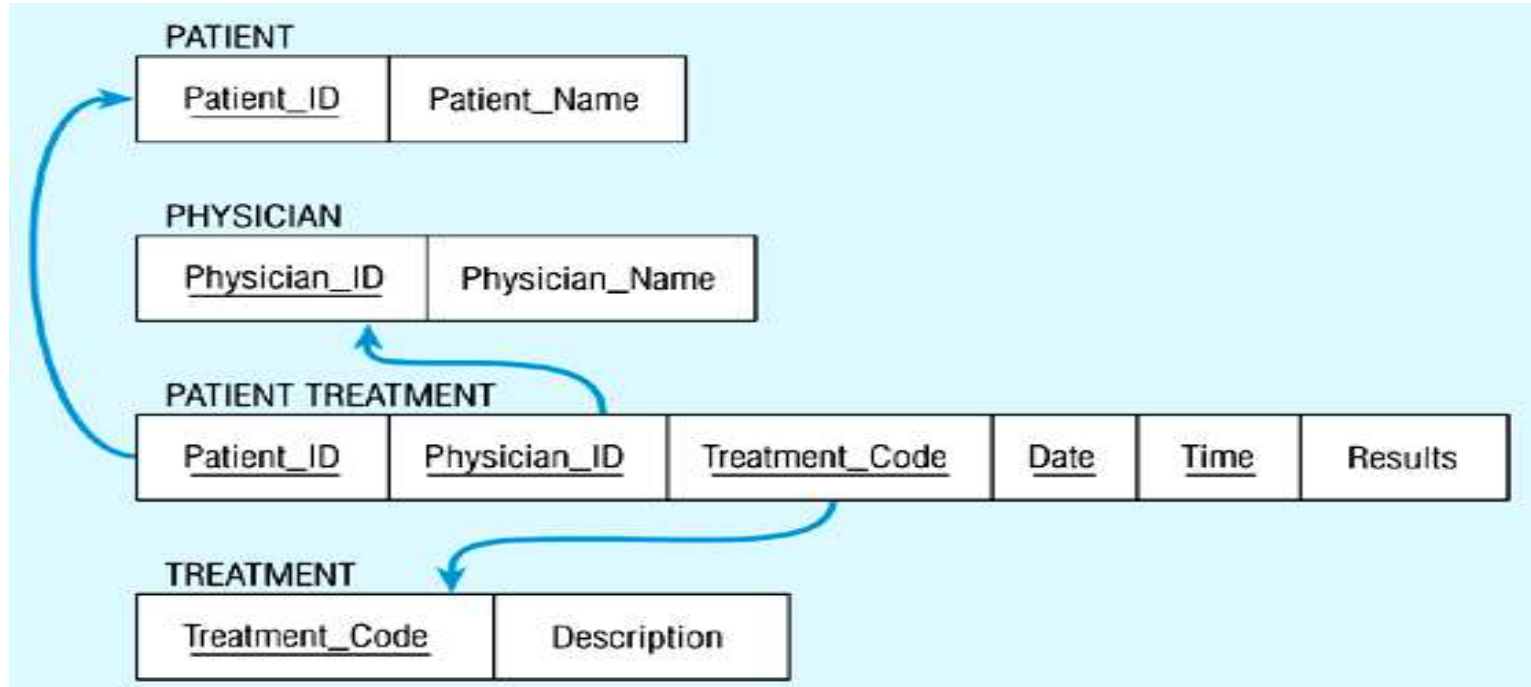

<u>ID</u>	Name
1	Nam
2	Dũng
3	Huy

FromEmployeeID	ToEmployeeID	Content	Date
1	2	Hello A, Khỏe ko a?	2/19/2023
2	1	Hello E, A vẫn khỏe! thế còn em?	2/19/2023
1	2	Có tiền Em vay ít?	2/19/2023
2	1	A cho chú số vợ anh nhé ;))	2/19/2023

Converting ER Model to relational schema

Shopee ER Model to database chema
